

Nature of Matter : Elements, Compounds, and Mixtures

8

Probe and ponder

- Which of the entities in the picture above consist of matter, and which of them do not?
- How can elements be combined to form a compound?
- How could the discovery of a compound that absorbs carbon dioxide from the air contribute to solving environmental challenges?
- Share your questions

_____?
_____?

Have you ever wondered what the world around you is made of? Look around! The staircase you use, the air you breathe, the water in your bottle, the food in your lunch box, the clothes and shoes you wear, the book you read, the trees outside, the ball you play with and even the stick you carry—all of these are examples of **matter**, which you have learnt in earlier grades.

You have also learnt that all these things are made up of tiny particles. Most of the things around us are not made of just one substance; rather they are made up of two or more substances mixed together. Let us now understand how different substances come together to form mixtures.

8.1 What Are Mixtures?

Fig. 8.1: Poha

Fig. 8.2: Sprout salad

Have you ever wondered what makes your *poha* (Fig. 8.1) so delicious or how to make the perfect sprout salad? While these dishes may seem very different, they share something in common—they are both made by mixing several ingredients. We **observe** the mixing of substances in everyday life. Sugar dissolved in water is also a mixture, and so are soups and lemonade.

When two or more substances are mixed, where each substance retains its properties, it is called a **mixture**. The individual substances that make up a mixture are called its **components**. The components of a mixture do not react chemically with each other. In some mixtures, the components—like green gram, chickpeas, onion, and tomato in a sprout salad (Fig. 8.2), are easy to see. Such mixtures, where the different components are generally visible with the naked eye or with a magnifying device, are **non-uniform** in nature. Can you **identify** a few more examples of non-uniform mixtures around you?

On the other hand, some mixtures have components that cannot be seen separately even with the help of a microscope. For example, sugar and water particles cannot be seen separately in their mixture. Such types of mixtures, where the components are evenly distributed and cannot be distinguished, are **uniform** in nature (Fig. 8.3). Can you list a few uniform mixtures?

Fig. 8.3: Uniform mixture of sugar and water

- Stir continuously to make a solution of calcium hydroxide. This solution is called lime water.
- Filter it and observe its colour.
- Leave this colourless solution in a petri dish for a few hours (Fig. 8.5a).
- Keep stirring the solution at regular intervals.
- What do you observe (Fig. 8.5b)?
- Does it turn milky?

Can you **explain** why the solution has turned milky?

You know that lime water turns milky when carbon dioxide reacts with calcium hydroxide to form calcium carbonate (insoluble tiny white particles) and water (Fig. 8.5). Since lime water turns milky when exposed to air, this activity **demonstrates** the presence of carbon dioxide in the air.

Calcium hydroxide + Carbon dioxide → Calcium carbonate + Water

Apart from gases, have you ever observed anything else present in the air? Have you ever noticed tiny shining particles moving in a beam of sunlight entering a dark room through a small opening? What are these particles?

Activity 8.2: Let us explore

- Take a black sheet of paper. Ensure that it is free from any visible dust particles.
- Place the black sheet of paper undisturbed near an open window (Fig. 8.6a), or in the garden, for a few hours.
- What do you observe?

You may notice tiny particles settled on its surface. You may use a magnifying glass to **examine** the particles more closely (Fig. 8.6b).

This shows that dust particles are suspended in the air. They are not an integral part of the air and are considered pollutants. The nature and the number of dust particles in the air may vary from time to time and from place to place.

A step further

The major pollutants present in the air are particulate matter (dust, soot) and gases like carbon monoxide, ozone, nitrogen dioxide, and sulfur dioxide. The **air quality index** (AQI) is a tool used to describe the air quality.

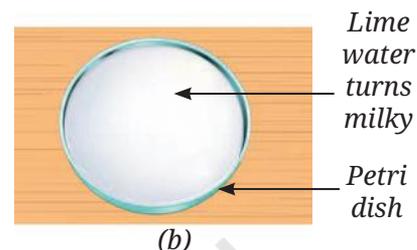

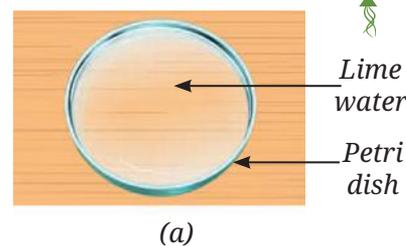

Fig. 8.5: Lime water turns milky in the presence of carbon dioxide

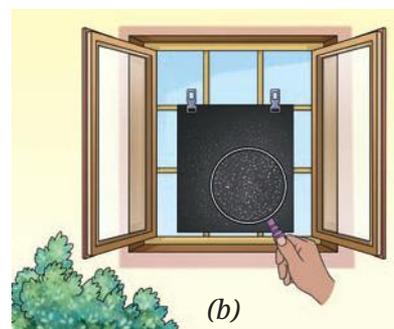

Fig. 8.6: Black sheet of paper (a) with no dust particles; (b) with dust particles

In science, however, a pure substance is the one that has no other substance present in it. For a scientist, even these products that look pure can be considered **impure** if they are made of more than one substance.

A pure **substance** is a kind of matter that cannot be separated into other kinds of matter by any physical process. When a scientist says that something is pure, it means that the substance consists of the same type of particles.

A step further

According to science, how would you **classify** milk, packed fruit juice, baking soda, sugar, and soil—as mixtures or pure substances?

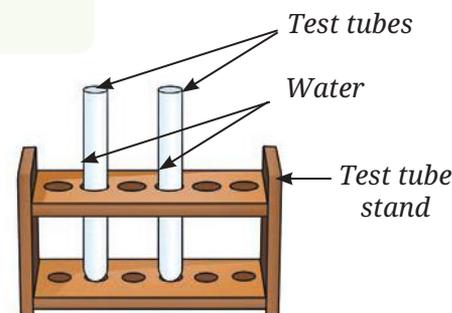

8.3 What Are the Types of Pure Substances?

Recall the different states of water that you studied in *Curiosity*, Grade 6. What happened when water was cooled or heated? We observed that on cooling water gets converted into ice, and on boiling it gets converted into vapour. We can get back water up on heating ice or cooling water vapour. It shows that during these processes, the particles of water remain the same. Now, let us **perform** another activity in which we pass electricity through water and observe its effect.

Activity 8.3: Let us experiment (Demonstration activity)

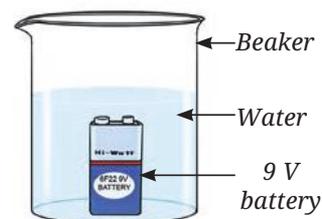

Safety first

This activity must be performed under the supervision of the teacher. Be careful while handling sulfuric acid. Do not use lithium-ion battery.

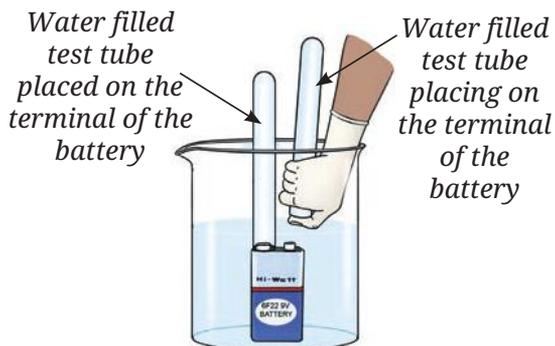

(a) Test tubes filled with water

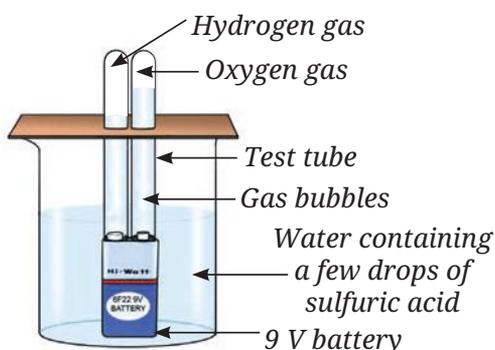

- Collect two small test tubes, a beaker or a glass tumbler, and a 9 V battery.
- Fill 2/3rd of the beaker with water and add a few drops of dilute sulfuric acid to it.
- Fill both the small test tubes completely with water taken from the beaker (Fig. 8.8a).
- Place a 9 V battery inside the beaker (Fig. 8.8b).
- Without spilling the water, carefully place the water-filled test tubes on each of the terminals of the battery (Fig. 8.8c).

(b) 9 V battery placed inside the beaker containing water

(c) Water filled test tubes placing over the terminals of the battery

(d) Gases collected in the test tubes

Fig. 8.8: Passing electricity through water

- Wait for a few minutes.
- Do you observe the formation of any gas bubbles at both the terminals inside the test tubes?
- Let it continue for 10–15 minutes.
- Observe the volume of gas collected in each test tube (Fig. 8.8d).
- Is the volume of the gas collected the same in both the test tubes?
- Remove these test tubes one-by-one carefully.
- Test these gases one-by-one by bringing a burning candle close to the mouth of the test tubes.
- What happens in each case?
- Which gas is present in each test tube?

Can these collected gases be water vapour?

These gases are not water vapour otherwise they would have condensed back to form water. Let us try to identify these gases.

Safety first

Perform gas testing with care. Maintain a safe distance from the set-up.

To test the gases present in the two test tubes, bring a burning candle near the mouth of each test tube. A pop sound can be heard from one, indicating the presence of hydrogen gas (Fig. 8.9a). In the other test tube, the flame of the burning candle will glow brighter, confirming the presence of oxygen gas (Fig. 8.9b).

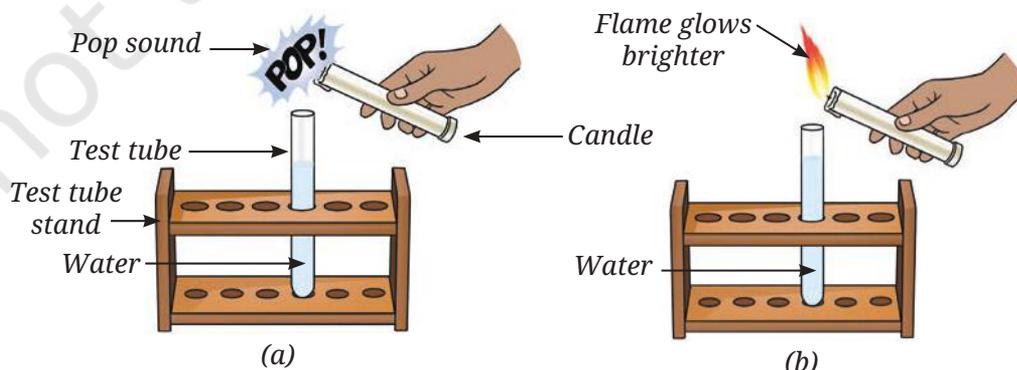

Fig. 8.9: Testing the nature of gas (a) hydrogen; (b) oxygen

From Activity 8.3, we can **infer** that water is composed of two different constituents—hydrogen and oxygen.

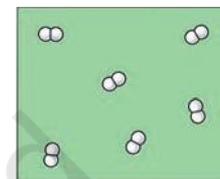

Ever heard of ...

When electric current is passed through water, it breaks down into hydrogen and oxygen. Is this a chemical change or a physical change? Recall *Curiosity*, Grade 7, chapter ‘Changes Around Us: Physical and Chemical’.

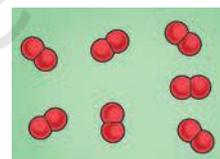

8.3.1 Elements

The two substances hydrogen and oxygen formed in Activity 8.3, are pure substances and are termed as **elements**. Each element is made up of identical particles called atoms. These particles are different from the particles of any other element. Elements are substances that cannot be further broken down into simpler substances. They are the building blocks of all matter. Some other examples of elements are gold, silver, sulfur, carbon, etc.

(a)

(b)

A step further

The atoms of most of the elements cannot exist independently. Two or more such atoms combine and form a stable particle of that element called a molecule. For example, two atoms of hydrogen combine to form one molecule of hydrogen. Similarly, two atoms of oxygen combine to form one molecule of oxygen (Fig. 8.10).

Fig. 8.10: Depiction of molecules of (a) hydrogen; (b) oxygen

Elements can be classified into **metals** and **non-metals**. You have already studied that gold, silver, magnesium, iron, and aluminium are metals, whereas carbon, sulfur, hydrogen, and oxygen are non-metals. Isn't it interesting to know that some elements like silicon and boron have intermediate properties between those of metals and non-metals? They are called **metalloids**, about which you will learn in higher grades.

A step further

- ◆ The number of elements known at present is 118, and most of them exist in a solid state.
- ◆ Eleven elements exist in a gaseous state at room temperature, all of which are non-metals like oxygen, helium, nitrogen, etc.
- ◆ Only two elements are liquid at room temperature—mercury, which is a metal and bromine, which is a non-metal.
- ◆ Although gallium and caesium are solid elements, they become liquid at a temperature around 30 °C (303 K) and turn into liquid.

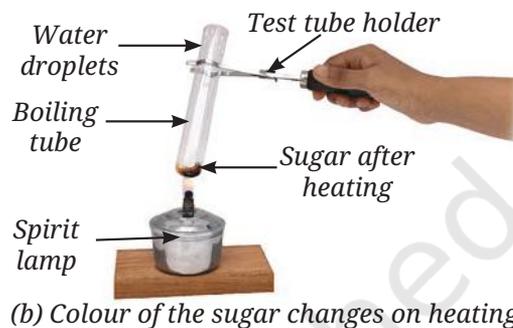

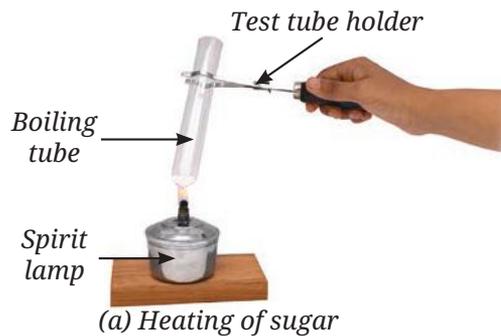

As you heat the sugar, it turns brown (Fig. 8.12b). Later, it begins to char, i.e., it turns blackish (Fig. 8.12c).

You will find small droplets of water inside the boiling tube near its open end. Where did this water come from? Was it in the dry sugar, or did it come by the condensation of water vapour in the air?

Since we are heating the tube, the water must have come from the dry sugar and not from the air. Can you **predict** what is left behind? Charcoal (carbon) is left behind in the boiling tube. You can scoop it out in a watch glass (Fig. 8.12c) and explore if it burns like coal.

Sugar decomposes on heating and gives carbon and water. As you know, water consists of hydrogen and oxygen. Hence, sugar cannot be an element. It may be stated that sugar is a chemical compound consisting of the elements carbon, hydrogen, and oxygen.

Let us explore more about compounds.

(c) Charcoal placed on a watch glass
Fig. 8.12: Heating sugar in a boiling tube

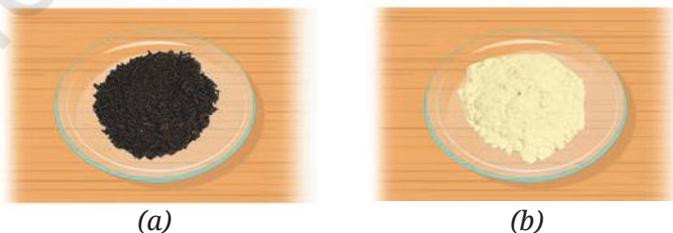

Activity 8.5: Let us experiment (Demonstration activity)

Safety first

This activity may be demonstrated under the supervision of the teacher. It may be performed in a fume hood or a well-ventilated area. Do not inhale the gases.

- Take 5.6 grams of iron filings (Fig. 8.13a) and 3.2 grams of sulfur powder (Fig. 8.13b) on a watch glass. Observe them carefully.

(a) Iron filings; (b) Sulfur powder
Fig. 8.13: (a) Iron filings; (b) Sulfur powder

made of elements, hydrogen and oxygen. Elements like iron and aluminium are used to construct bridges, buildings, and vehicles.

Understanding these concepts is not just about recognising what surrounds us; it is also the key to innovation. For instance, chemists study how elements combine to create compounds, enabling them to invent life-saving medicines and vaccines to fight diseases. This knowledge also helps in the creation of fertilisers thereby enhancing crop production that feeds the ever-increasing human population globally.

Engineers and material scientists rely on their understanding of compounds and mixtures to design materials with unique properties. For example, they have developed alloys like stainless steel, which is stronger and more durable than pure iron. Wood, steel, and concrete, which are used as building materials, are all mixtures.

You learnt that various metals are obtained from minerals. Let us learn about these minerals.

A step further

Fig. 8.21

An example of a ‘wonder’ material developed by material scientists is graphene aerogel. This is made from carbon and is said to be the lightest material on earth. It is so light that even grass can hold it (Fig. 8.21). It is highly porous and therefore, has a high absorbing capacity. For this reason, it can potentially be used as an environmental cleaner, for example, to clean up oil spills in both seas and on land. It is useful in fabricating energy-saving devices and special coatings for buildings.

8.5 What Are Minerals?

Most rocks are a mixture of **minerals**, which can be viewed with the eyes, or by using a magnifying glass or a microscope. Some of the minerals are called native minerals, which are pure elements and not compounds. These can be metals, such as gold, silver, copper, etc., or non-metals like sulfur, carbon, etc.

Most of the minerals are compounds made up of more than one element. Some common examples of minerals include quartz, calcite, mica, pyroxene, and olivine (Fig. 8.22). Many things that we use in our everyday life are made up of minerals or elements extracted from minerals. For example, cement is made from calcite, quartz, alumina, and iron oxide, which are minerals or are obtained from minerals. Talcum powder is made from the mineral talc.

Fig. 8.22: Some minerals

Keep the curiosity alive

1. Consider the following reaction where two substances, A and B, combine to form a product C:

Assume that A and B cannot be broken down into simpler substances by chemical reactions. Based on this information, which of the following statements is correct?

- (i) A, B, and C are all compounds and only C has a fixed composition.
 - (ii) C is a compound, and A and B have a fixed composition.
 - (iii) A and B are compounds, and C has a fixed composition.
 - (iv) A and B are elements, C is a compound, and has a fixed composition.
2. Assertion: Air is a mixture.
Reason: A mixture is formed when two or more substances are mixed, without undergoing any chemical change.
 - (i) Both Assertion and Reason are true and Reason is the correct explanation for Assertion.
 - (ii) Both Assertion and Reason are true, but Reason is not the correct explanation for Assertion.
 - (iii) Assertion is true, but Reason is false.
 - (iv) Assertion is false, but Reason is true.
 3. Water, a compound, has different properties compared to those of the elements oxygen and hydrogen from which it is formed. Justify this statement.
 4. In which of the following cases are all the examples correctly matched? Give reasons in support of your answers.
 - (i) Elements — water, nitrogen, iron, air.
 - (ii) Uniform mixtures— minerals, seawater, bronze, air.
 - (iii) Pure substances— carbon dioxide, iron, oxygen, sugar.
 - (iv) Non-uniform mixtures — air, sand, brass, muddy water.
 5. Iron reacts with moist air to form iron oxide, and magnesium burns in oxygen to form magnesium oxide. Classify all the substances involved in the above reactions as elements, compounds or mixtures, with justification.

Prepare some questions based on your learnings so far ...

6. Classify the following as elements, compounds, or mixtures in Table 8.3.

Carbon dioxide, sand, seawater, magnesium oxide, muddy water, aluminium, gold, oxygen, rust, iron sulfide, glucose, air, water, fruit juice, nitrogen, sodium chloride, sulfur, hydrogen, baking soda.

Table 8.3

Elements	Compounds	Mixtures

Identify pure substances amongst these and list them below.

Pure substances

7. What new substance is formed when a mixture of iron filings and sulfur powder is heated, and how is it different from the original mixture? Also, write the word equation for the reaction.

8. Is it possible for a substance to be classified as both an element and a compound? Explain why or why not.

9. How would our daily lives be changed if water were not a compound but a mixture of hydrogen and oxygen?

10. Analyse Fig. 8.24. Identify Gas A. Also, write the word equation of the chemical reaction.

11. Write the names of any two compounds made only from non-metals, and also mention two uses of each of them.

12. How can gold be classified as both a mineral and a metal?

Discover, design, and debate

- Design and create comic strips from real-life examples to differentiate between elements, compounds, and mixtures with diagrams and illustrate their properties and uses.
- Search for discoveries of some elements (such as phosphorus, sodium), compounds (such as penicillin) and mixtures (such as brass, bronze, stainless steel). Present your findings in the class.
- Let us search: Read labels on items like detergents or snacks, and try to list the mixtures and compounds they contain.
- Work in groups: Each group will pretend to be in the role of either an element, a compound, or a mixture. Debate which category among them is the most important.
